	$\tilde{t}_1\tilde{t}_1, \tilde{t}_1 \rightarrow W\tilde{\chi}_1^0$	1 $e, \mu$	2 b	Yes	20.3	$\tilde{t}_1$ 285 GeV	m( $\tilde{q}$ )=m( $\tilde{q}$ ), m( $\tilde{q}$ )=0, sleptons decoupled ATLAS-CONF-2013-093
Long-lived particles	$\tilde{t}_1\tilde{t}_1, \tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$	4 $e, \mu$	0	Yes	20.3	$\tilde{t}_1$ 620 GeV	m( $\tilde{q}$ )=m( $\tilde{q}$ ), m( $\tilde{q}$ )=0, m( $\tilde{t}_1, \tilde{t}_2$ )=0.5(m( $\tilde{q}$ ))+m( $\tilde{q}$ ) 1405.5086
	Direct $\tilde{\chi}_1^0\tilde{\chi}_1^0$ prod., long-lived $\tilde{\chi}_1^0$	Disapp. trk	1 jet	Yes	20.3	$\tilde{\chi}_1^0$ 270 GeV	m( $\tilde{q}$ )=m( $\tilde{q}$ )=160 MeV, $\tau(\tilde{\chi}_1^0)=0.2 \text{ ns}$ ATLAS-CONF-2013-069
	Stable, stopped $\tilde{g}$ R-hadron	0	1-5 jets	Yes	27.9	$\tilde{g}$ 832 GeV	m( $\tilde{q}$ )=100 GeV, $10 \mu\text{s} < \tau(\tilde{g}) < 1000 \text{ s}$ 1310.5584
	GMSB, stable $\tilde{\tau}, \tilde{\chi}_1^0 \rightarrow \tilde{\tau}\tilde{\chi}_1^0 + \tau(e, \mu)$	1-2 $\mu$	-	-	15.9	$\tilde{\tau}$ 475 GeV	$10 < \text{tan}\beta < 50$ ATLAS-CONF-2013-058
GMSB, $\tilde{\chi}_1^0 \rightarrow \tilde{\chi}_1^0 + \tilde{g}$ , long-lived $\tilde{\chi}_1^0$	2 $\gamma$	-	Yes	4.7	$\tilde{\chi}_1^0$ 230 GeV	$0.4 < \tau(\tilde{\chi}_1^0) < 2 \text{ ns}$ 1304.6310	
$\tilde{q}\tilde{q}, \tilde{\chi}_1^0 \rightarrow q\tilde{q}\tilde{\chi}_1^0$ (RPV)	1 $\mu$ , displ. vtx	-	-	20.3	$\tilde{q}$ 1.0 $\tau$		
RPV	LFV $pp \rightarrow \tilde{\nu}_e + X, \tilde{\nu}_e \rightarrow e + \mu$	2 $e, \mu$	-	-	4.6	$\tilde{\nu}_e$ 1.0 $\tau$	
	LFV $pp \rightarrow \tilde{\nu}_e + X, \tilde{\nu}_e \rightarrow e(\mu) + \tau$	1 $e, \mu + \tau$	-	-	4.6	$\tilde{\nu}_e$ 1.0 $\tau$	
	Bilinear RPV CMSSM	2 $e, \mu$ (SS)	0-3 b	Yes	20.3	$\tilde{g}, \tilde{g}$ 750 GeV	
	$\tilde{\chi}_1^0\tilde{\chi}_1^0, \tilde{\chi}_1^0 \rightarrow W\tilde{\chi}_1^0, \tilde{\chi}_1^0 \rightarrow e\tilde{\nu}_e, e\mu\tilde{\nu}_e$	4 $e, \mu$	-	Yes	20.3	$\tilde{\chi}_1^0$ 450 GeV	
Other	Scalar gluon pair, sgluon $\rightarrow q\tilde{q}$	0	4 jets	-	4.6	$\tilde{g}$ 100-287 GeV	
	Scalar gluon pair, sgluon $\rightarrow t\tilde{t}$	2 $e, \mu$ (SS)	2 b	Yes	14.3	$\tilde{g}$ 350-800 GeV	
WIMP interaction (D5, Dirac $\chi$ )	0	mono-jet	Yes	10.5	$M^2$ scale 704 GeV		

- SUSY probed at LHC up to  $\sim 1 \text{ TeV}$
- No signal found yet
- So, where is SUSY?
- Higher luminosity and energy of future LHC runs will certainly improve the reach
- Is this enough?

\*Only a selection of the available mass limits on new states or phenomena is shown. All limits quoted are observed minus 1 $\sigma$

# “Alternative SUSY”

- Alternative from the experimental point-of-view
  - high missing transverse momentum not necessary
    - R-parity violating (RPV) signatures
    - long-lived particles (LLP)
- Why overlooked so far?
  - R-parity always provides a dark matter candidate; in RPV in some cases (gravitino, axino)
  - signatures from stable particles require large effort to be probed
    - ATLAS & CMS optimised for promptly decaying particles
    - need to take care many aspects of analysis (trigger, reconstruction, non-collision background, ...) from scratch
  - difficult to organise RPV searches in coherent way
    - many couplings → many combinations of final states
    - prompt vs. delayed LSP decays
    - consider one non-zero coupling at a time versus complete RPV model

# R-parity violation

- R-parity:  $R = (-1)^{3(B-L)+2s} \rightarrow R = \begin{cases} +1, & \text{for SM particles} \\ -1, & \text{for superpartners} \end{cases}$

$$W_{Rp} = \underbrace{\lambda_{ijk} \hat{L}_i \hat{L}_j \hat{E}_k^C + \lambda'_{ijk} \hat{L}_i \hat{Q}_j \hat{D}_k^C}_{\text{L-number violating terms}} + \underbrace{\epsilon_i \hat{L}_i \hat{H}_u}_{\text{bilinear terms}} + \underbrace{\lambda''_{ijk} \hat{U}_i^C \hat{D}_j^C \hat{D}_k^C}_{\text{B-number violating terms}}$$

- R-parity conservation hinted but not required by proton stability
- Phenomenological consequences of RPV:
  - LSP may be charged and/or carry color (e.g. sleptons, squarks)
  - LSP is not stable
    - potentially long LSP lifetime
    - transverse missing energy in colliders may or may not be large

A whole new landscape of phenomenological possibilities opens up...

# Bottom-up approach: inclusive analysis

- All coupling types considered:  $\lambda$  (purely leptonic),  $\lambda'$ ,  $\lambda''$  (purely hadronic)
- Many combinations of objects in final state: 0, 1, 2 leptons, taus, b-jets
- Signal regions cover all space in terms of kinematic variables
- Limits set for many couplings yet for limited decay chains

CMS-PAS-SUS-12-027

# Target specific decay chain / coupling: 4 leptons

- Neutralino decays into 2 charged leptons and a neutrino
  - 4 charged leptons (flavours determined by  $\lambda_{ijk}$  choice)
  - RPV signal selection via Z-veto and effective mass
- RPV-optimised analysis enhances discovery reach yet much effort needed to cover more couplings

Phys. Rev. D. 90, 052001 (2014)

# Top-bottom approach: bilinear RPV

- Consider a well-motivated RPV model...
- Bilinear RPV introduces **neutrino masses** in an intrinsically supersymmetric way
  - EW symmetry is broken by Higgs and sneutrino VEVs
  - neutrinos mix with neutralinos
  - a “low-scale” seesaw mechanism renders neutrinos **massive**
- Direct connection between model phenomenology and neutrino parameters

$$W_{\text{bRPV}} = W^{\text{MSSM}} + \epsilon_i \hat{L}_i \hat{H}_u$$

$$V_{\text{soft}} = V_{\text{soft}}^{\text{MSSM}} - B_i \epsilon_i \tilde{L}_i H_u$$

$$\tan^2 \theta_{\text{atm}} \simeq \left| \frac{\Lambda_\mu}{\Lambda_\tau} \right|^2 \simeq \frac{BR(\tilde{\chi}_1^0 \rightarrow \mu^\pm W^\mp)}{BR(\tilde{\chi}_1^0 \rightarrow \tau^\pm W^\mp)}$$

- Well-defined LHC phenomenology thanks to constraints from neutrino measurements
- Large MET due to copious **neutrino** production  
→ conventional MET-based searches applicable to bRPV SUSY

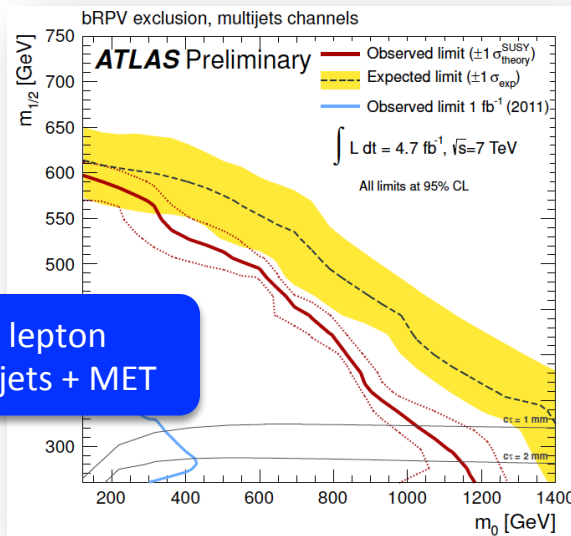

Valle, Hirsch, Porod, Romao, Diaz, *et al.*

# ATLAS results on bRPV SUSY

- So far, interpretation of results from searches targeting R-parity conserving SUSY in mSUGRA-bRPV

ATLAS-CONF-2012-140

JHEP 1406 (2014) 035

Possibilities for 13 / 14 TeV run (just some thoughts):

- embed bRPV couplings in an attractive SUSY scenario, e.g. natural pMSSM
- design analysis customised for such models (also sensitive to trilinear RPV)
- **What about other RPV models?** see e.g.:
  - L. Covi's talk on decaying dark matter [arXiv:1403.4923]
  - Y. Nakai's talk on warped natural SUSY [arXiv:1407.5095]

# RPV model: $\mu\nu$ SSM

- $\mu\nu$ SSM:  $\mu$ -from- $\nu$  Supersymmetric Standard Model
  - R-parity breaking terms
  - $\rightarrow$  **neutrino masses**
  - $\rightarrow$  **evades  $\mu$ -problem**
- Very rich phenomenology
  - many Higgs bosons and gauginos
  - $\rightarrow$  **enlarged Higgs sector can easily accommodate a 125-GeV Higgs boson**
  - long neutralino lifetimes  $\rightarrow$  **(extremely) displaced vertices**
  - **multileptons / multitaus**

Muñoz, López-Fogliani, Ruiz de Austri, Fidalgo, Roy, Ghosh, Dey *et al.*

Position of LSP decay  
in LHC detector

Ghosh, López-Fogliani, VAM, Muñoz, Ruiz de Austri,  
**Phys.Rev. D88 (2013) 015009**

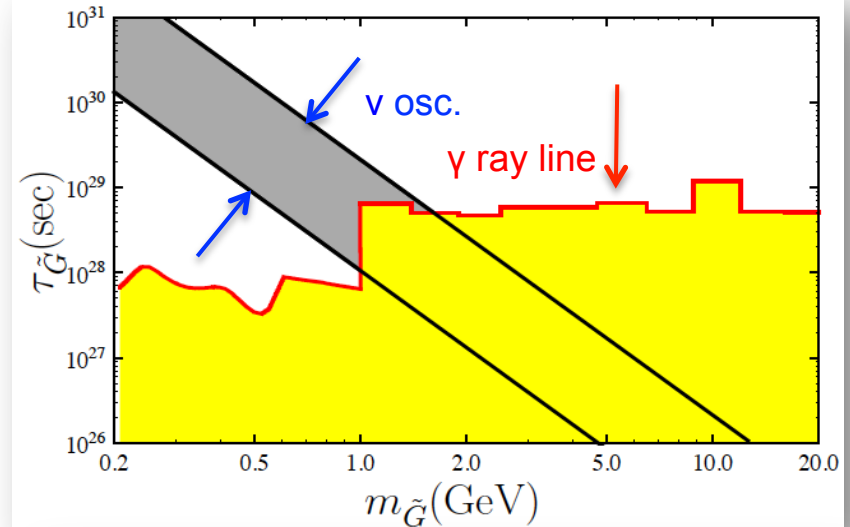

May serve as an inspiration for looking for other prompt or displaced signatures at 14-TeV LHC (other models may profit, too)

# What about RPV and dark matter?

- Gravitino LSP with cosmologically-long lifetime
  - signal: monochromatic gamma-rays
  - constrained by  $\tilde{G} \rightarrow \gamma\nu$ 
    - $\nu$ -oscillations
    - DM relic density  $\Omega_\chi h^2$
    - $\gamma$ -ray line searches
- If lightest neutralino is the NLSP

$$\begin{aligned}\tilde{\chi}_1^0 &\rightarrow h^0 \nu_i, & \tilde{\chi}_1^0 &\rightarrow W^\pm l_i^\mp, \\ \tilde{\chi}_1^0 &\rightarrow \gamma \nu_i, & \tilde{\chi}_1^0 &\rightarrow Z^0 \nu_i.\end{aligned}$$

- (Long-lived) neutralino can also decay to 3 fermions

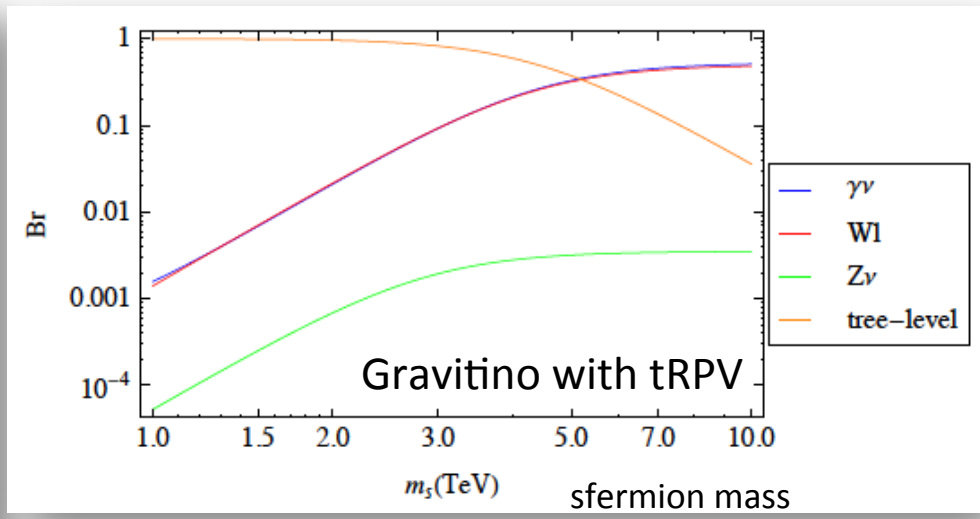

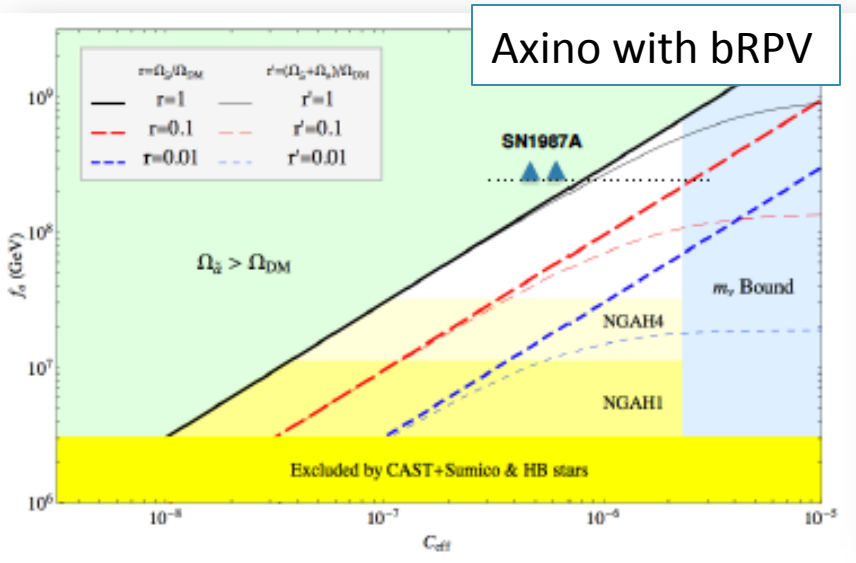

# Away from LHC: $\gamma$ -ray lines & RPV SUSY

- 130-GeV  $\gamma$ -line in Fermi-LAT
  - axino with bilinear RPV [Endo et al, PLB 721 (2013) 111]
  - gravitino with trilinear RPV [Liew, PLB 724 (2013) 88]
- Recently, 3.5 keV X-ray emission line observed in galaxy clusters
  - **axino with RPV** [Choi & Seto, PLB 735 (2014) 92; Liew, JCAP 1405 (2014) 044]
  - **gravitino, bino, or hidden sector photino in RPV** [Kolda & Unwin, PRD 90 (2014) 023535; Bomark & Roszkowski, PRD 90 (2014) 011701]

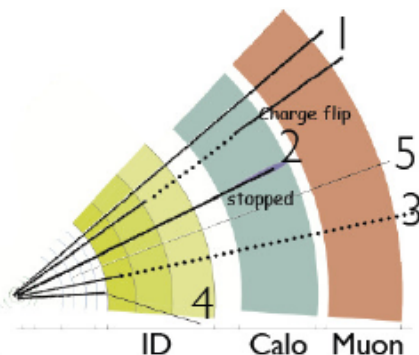

$$\tilde{G} \rightarrow \gamma \nu$$

Park, Kong, Park, PLB 733 (2014) 217

# Stable or metastable particles

- Long-lived decays of spartners possible in several frameworks, including
  - nearly conserved symmetry
    - e.g. long lived gluinos or squarks that hadronise before decaying  
→ R-hadrons in Split SUSY
  - low coupling between the particle and the final state
    - e.g. weak RPV couplings
  - Mass degeneracy between the particle and the final state
- Depending on the lifetime, different detection techniques involving various objects: tracks, photons, leptons, ...

(1) Slow, large  $dE/dx$

~ 1000 mm

(2) Slow, stopped

~ 100 mm

(3) Disappearing track

(4) Kinked track

~ 10 mm

(5) displaced track

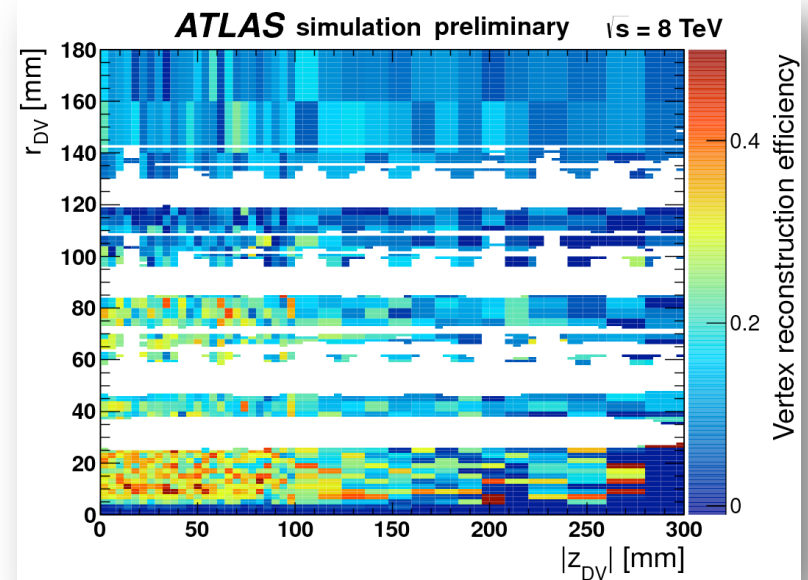

# Displaced vertices: analysis

- RPV: LSP decays 4 – 180 mm from the interaction point for couplings  $\lambda'_{2ij} \neq 0$
- Search for high-impact-parameter vertices:  $|\mathbf{d}_0| > 2 \text{ mm}$ 
  - trigger: high- $p_T$  muon
  - SM-particle late decays  $\rightarrow$  require high mass & high track multiplicity
  - overlap of high- $p_T$  track with hadronic interaction vertex  $\rightarrow$  veto to vertices reconstructed within regions of high-density material

ATLAS-CONF-2013-092

# Displaced vertices: results

- Number of events passing selected requirements except for  $m_{DV}$  and  $N_{DVtracks}$
- No data events observed in the signal region
- Upper exclusion limits at 95% CL
- Depend on masses and LSP lifetime
- Excluded:  $\sigma \times BR > 0.8 - 5.4 \text{ fb}$

ATLAS-CONF-2013-092

For 13 / 14 TeV run:

- dedicated DV trigger
- new final states (also for Run-I final analysis): e+jets, v+jets, ...
- new “complete” RPV models to motivate/interpret analysis (not just  $\lambda'$  couplings)

# Disappearing track search

$$\tilde{\chi}_1^\pm \rightarrow \tilde{\chi}_1^0 + \pi^\pm$$

- Meta-stable next-to-lightest particles may be created, fly some distance, and disappear / decay within the inner detector
- Searching for tracks with:
  - inner silicon detector: Well measured
  - **outer straw tracks (TRT):** Low (<5) number of hits

Chargino mass below 270 GeV excluded in decoupled Anomaly Mediated SUSY Breaking (AMSB)

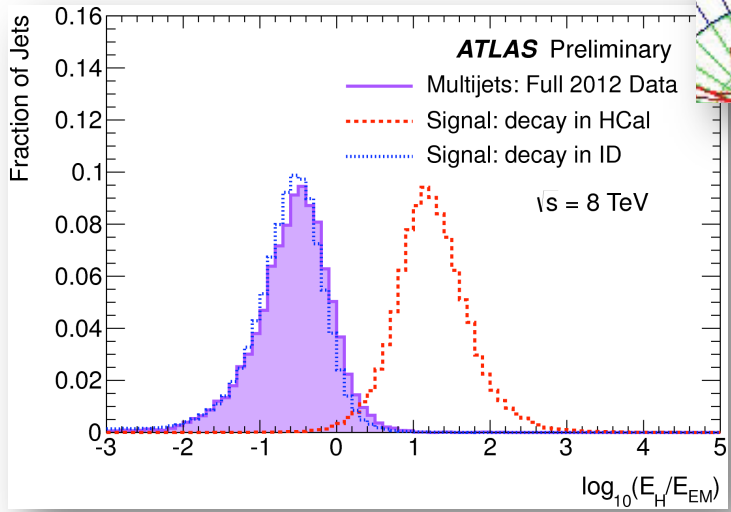

Phys. Rev. D 88 (2013) 112006

In view of the ATLAS inner detector upgrade in future HL-LHC (no TRT), such analyses have to be completely redesigned  
 → should get the most out of Run II

# Non SUSY LLP: Hidden Valley neutral particle

- Hidden Valley (HV) weakly coupled to SM via heavy communicator scalar  $\Phi_{HS}$ 
  - $\Phi_{HS}$  Higgs or a Higgs-like scalar
  - HV can alter the branching fractions for Higgs decay
- Signature: If  $\pi_v$  long-lived, will give rise to final states with  $\pi_v$  decaying in **hadronic calorimeter (HCal)** or the outer edge of **electromagnetic (EM) calorimeter**

ATLAS-CONF-2014-041

$m_\phi = 126 \text{ GeV}$

No significant excess was observed  
 → limits set in Hidden Valley scenario  
 → analysis may be sensitive to other (SUSY) scenarios,  $\mu\nu\text{SSM}$  ?

# MoEDAL experiment

- One step further: dedicated experiment at LHC to observe highly-ionising (meta-)stable states
  - monopoles, dyons
  - **SUSY stable particles**
  - multiply-charged particles, e.g. doubly charged Higgs
  - black-hole remnants, Q-balls, ...
- Complementary to ATLAS & CMS experiments

MoEDAL is unlike any other LHC experiment:

- mostly passive detectors; no trigger; no readout
- the largest deployment of passive **Nuclear Track Detectors** at an accelerator
- the 1<sup>st</sup> time **trapping detectors** will be deployed as a detector

MoEDAL detectors are being installed to be ready for LHC Run II

# Summary & outlook

- R-parity violating and long-lived decays in SUSY
  - lead to collider signatures not predicted by conventional RPC searches
  - effort to cover them with dedicated analyses
  - in Run I we have barely scratched the surface of it
- Search approaches for 14-TeV LHC
  - reinterpretations of existing RPC analyses
    - help identify uncovered regions and carry out RPV-targeted analysis
  - prompt RPV searches
    - typically target high multiplicity final states & resonant production
    - probe more final states
  - searches for long-lived decays
    - exploiting the full potential of the detector
    - new operating conditions may require redesign existing analyses/triggers...
    - new ideas for theorists welcomed!!

... for 13-14 TeV  
run in 2015

Backup...

# How do we search for SUSY at LHC?

- SUSY (more than) duplicates spectrum of particle states w.r.t. Standard Model
- Simplest extension of SM (MSSM) has  $> 100$  new parameters
- Sparticles decay into (b/c-)jets, leptons, taus, photons, invisible (MET), ...

- How do we decide on what to search for?
- How to interpret the results?

# SUSY @ LHC: The strategy

## Theoretical model space

breaking mechanism, R parity, MGUT unification, ..  
(N)MSSM, mSUGRA, GMSB, ...

### Top down

Define model  
and search for it  
in suitable final  
states

### Bottom up

Define topology (decay  
chain) and interpret  
results in  $(m_X, m_Y)$  plane  
→ simplified topologies

## Experimental signature space

MET ? + n jets + m leptons, taus, Meff, mT, ...

# SUSY @ LHC: The organisation

Following previous paradigm, we divide analyses into separate<sup>(\*)</sup> signatures

- R-parity conserving (RPC) signatures:
  - sparticles produced in pairs, each decays to (WIMP) LSP, mostly lightest neutralino or gravitino
  - one invisible LSP per decay chain → MET
- R-parity violating (RPV) signatures:
  - resonances or multijets / multileptons: single sparticle production or LSP decay
  - Displaced vertices from late LSP decay
- Long-lived particles from:
  - weak couplings, e.g. RPV, gravitino
  - heavy mediator sparticles, e.g., heavy squarks in split SUSY
  - mass degeneracy, e.g.  $m(\text{chargino}) \sim m(\text{LSP})$  in AMSB

---

(\*) Limits not clearly defined,  
e.g. RPV delayed decays

# SUSY searches @ LHC

**Strong-production channels**

- Copious production at hadron colliders
- $E_T^{\text{miss}}$ -based generic search channels
- Plus more exotic channels

**Third-generation sparticle searches**

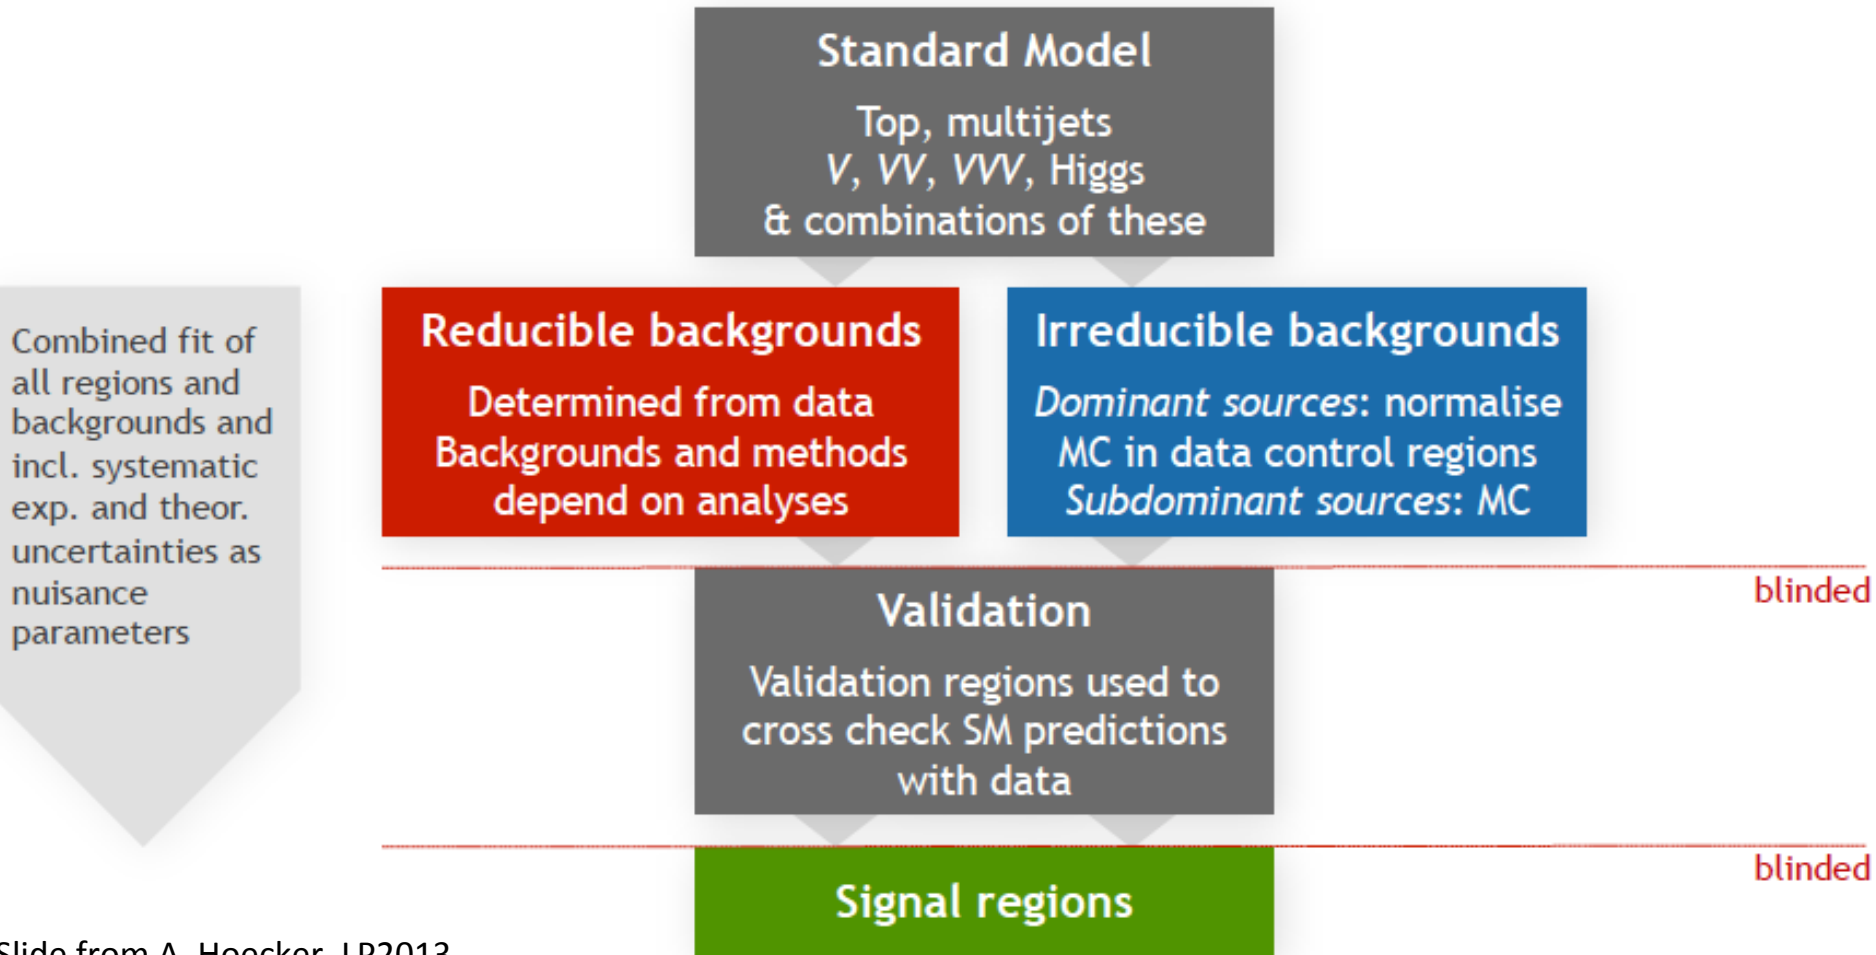

- Expected from naturalness to be  $O(< \text{TeV})$
- Expected lighter than other squarks due to mixing
- Can search for more specific final states

**Leptons/photons searches**

- colored partners too heavy  $\rightarrow$  direct gaugino production
- pertinent for gauge-mediated models

# SUSY @ LHC: The technique

Background estimation mostly based on data-driven techniques

# What about dark matter?

- Gravitino LSP with cosmologically-long lifetime
  - signal: monochromatic gamma-rays
  - constrained by  $\tilde{G} \rightarrow \gamma\nu$ 
    - $\nu$ -oscillations
    - DM relic density  $\Omega_\chi h^2$
    - $\gamma$ -ray line searches
- If lightest neutralino is the NLSP

$$\begin{aligned} \tilde{\chi}_1^0 &\rightarrow h^0 \nu_i, & \tilde{\chi}_1^0 &\rightarrow W^\pm l_i^\mp, \\ \tilde{\chi}_1^0 &\rightarrow \gamma \nu_i, & \tilde{\chi}_1^0 &\rightarrow Z^0 \nu_i. \end{aligned}$$

- (Long-lived) neutralino can also decay to 3 fermions
